[Analysis of Single-channel Maintenance Costs](#) Sep 02 2021 This thesis is a study of certain costs relevant to the repair of process line equipment. A specific production configuration is studied through computer simulation and statistics. The significance of the simulated costs are investigated and related to practical production problems. Costs relevant to the "permanent repair" of production equipment on the single-channel of an n-one-n production configuration are examined. A piece of equipment is assumed to be "permanently repaired" if it is modified or replaced, thus halting the breakdowns previously plaguing the machine. An n-one-n production configuration is a group of process lines (multi-channel), each manufacturing the same product, supplying a single process line (single-channel) with raw materials which in turn are used to supply dependent multi-channel process lines downstream with raw materials. Costs deemed important to the permanent repair of single-channel production equipment are: 1. the cost of breakdown repair, 2. the cost of single-channel idle time, 3. the cost of downstream multi-channel idle time due to single-channel breakdowns, and 4. the cost of additional in-process inventory required to prevent the costs of (2) and (3). Computer simulation is used to analyze the impact of single-channel breakdowns. The computer model simulates levels of single-channel idle time, ranging from 50% to 15% to reveal the effects of single-channel disrepair on the downstream multi-channel. The application of the study is based on data from an aluminum fabrication plant. The upstream multi-channel is where ingots are cast out of molten aluminum, the single-channel is where these ingots are rolled into coils, and the downstream multi-channel is where the coils are fabricated into forms desired by customers, such as corrugated metal or small widths of metal. Two key costs are found to be most important to the permanent repair decision: (1) the cost of single-channel idle time due to breakdowns, and (2) the cost of repairing a breakdown each time it occurs. These two costs comprise 84% of all expense resulting from breakdowns. In-process inventory is also very important to the operation of the plant. Without it, downstream idle time would occur and millions of dollars of sales would be lost due to order cancellations from delivery delays. Since every production system will have unique costs and individual characteristics, the actual cost findings of this study are not universally applicable. However, the methods used in deriving these costs are applicable to other plants having an n-one-n production configuration. The observations and techniques presented are a step towards improved decision making in maintenance, a topic which merits attention but has been partially ignored to date.

[Army Corps of Engineers](#) Dec 05 2021 The Corps operates over 700 dams, which are aging and may require major repairs to assure safe operation. At some dams, sponsors that benefit from dam operations share in the cost of operating and repairing these dams based on original congressional authorizations for dam construction or subsequent agreements with the Corps. Since 2005, the Corps initiated an estimated \$5.8 billion in repairs at 16 dams with urgent repair needs; sponsors are to share repair costs at 9 of these dams. GAO was asked to examine cost sharing for Corps dam safety repairs. This report examines how, over the last 10 years, the Corps (1) determined cost sharing and (2) communicated with sponsors regarding cost sharing. GAO reviewed relevant laws and Corps regulations; analyzed dam safety projects' documentation for the 16 dams the Corps selected for repairs since 2005; conducted site visits to a non-generalizable sample of three dams based on cost share determinations and range of sponsors; and interviewed Corps officials and sponsors.

It analyses which of Limberg's and Schmidt's contributions was the most prominent and whether either was the genesis of an evolutionary development of replacement price valuations. This analysis is apposite. History indicates we will experience further periods of inflation and accompanying debate on the serviceability of accounting proposals to incorporate the financial effects of price and price-level changes.

[Discard/Repair Cost \(DIREC\) Model Repair Versus Throwaway Printed Circuit Cards and Modules](#) Dec 17 2022 Discard versus repair policies have been subjected to

numerous studies in attempt to prove or disprove the specific policy. This study is an attempt to revise and develop a model in which total parameters involved may be considered. For example, acquisition cost is a single parameter against which total cost of repair may be played in a model. This is true since once an item is repaired and returned to the pipeline it is subjected to the same cost effects as a newly acquired item. This report discusses the total cost of repair to include the return of unserviceable items to a repair facility, test and repair of the items, and return as serviceable to the pipeline. The parameters involved are discussed in a decision model. The objective of the decision model is to determine cost effectiveness of discard or repair and establish policy. A spin-off of the model is that analysis of output against real time data permits determination of effectiveness of earlier decisions as well as examination of system effectiveness in meeting reliability goals. Keywords include: Systems analysis, Cost analysis, Discard-repair cost evaluation, Repair cost evaluation modeling, Maintenance evaluation modeling.
